In digital communication physical transfer of data occurs in the form of digital bit stream i.e 0 or 1 over a point-to-point or point-to-multipoint transmission medium. In digital communication the digital transmission data can be broken into packets as discrete messages which is not allowed in analog communication.

Analog input pins measure a range of voltages on a pin. In the below picture of the Arduino Uno Board, you can see where the Digital / Analog pins are on the board. Digital and Analog Pins. To read digital input Arduino uses a function called digitalRead() and it tells you if a voltage on a pin is HIGH (5volts) or LOW (0) volts.

However, when analog devices are involved, interfacing becomes much more complex. What is needed is a way to electronically translate analog signals into digital (binary) quantities, and vice versa. An analog-to-digital converter, or ADC, performs the former task while a digital-to-analog converter, or DAC, performs the latter.

### Analog and digital technology - What's the difference?

Digital Signal - A digital signal is a signal that represents data as a sequence of discrete values; at any given time it can only take on one of a finite number of values. Analog Signal - An analog signal is any continuous signal for which the time varying feature of the signal is a representation of some other time varying quantity i.e., analogous to another time varying signal.

It just shows an analog input, and its equivalent digital output. The example shown is an N-bit ADC. N is typically anything from 6 to 24, with common ones being 8, 10, 12 or 16. The input is a voltage, with a range of 0 up to some maximum value that depends on the actual ADC. Given that with N-bits there can be  $2^N$  possible digital values ...
